Description

use case:

I have a complex projects hierarchy for the company (many diversified activity lines, many groups of projects).
And I want to have a common project for user requests and claims, and to have ability to share versions from any needed project to that common project.
At present, I can only share with a tree, or a whole list of projects - but I don't want - cause it will cause an ambiguous list of common versions in every project.

We manage software evolution through "Redmine Project" and so we define Versions for these softwares.
Nevertheless, we need to track specific evolution project of these softwares under a different "Redmine Project" especially for time tracking.
I'd like to link issues of these evolutions projects to versions of the classical software project.
