Resolution:			**Affected version:**	

Description

Recently my company was performing a big *Redmine* deploy (4.2.X with *SQL Server*). After sometime users started to complain about issue hierarchy getting corrupted.

We made a research and it turns out there is a workaround in issue nested set locking for *SQL Server* which is behaving wrong sometimes (when multiple users are editing same issue trees). This is a BIG thing and is really surprising that there isn't a word about in the Installation guide. I think there should be a noticeable information that the only **production ready** database back-ends are *MySQL 5.5* and *PostgreSQL 9.2 +*.
